UNIFORM EDITION

RUDDER ON SERIES

Bound in blue buckram and gold, 32mo, illustrated

ON YACHTS AND YACHT HANDLING. By Thomas Fleming Day. Price $1.

ON MARINE MOTORS AND MOTOR LAUNCHES. By E. W. Roberts. Price $1.

SOUTHWARD BY THE INSIDE ROUTE. Price $1.

ON YACHT ETIQUETTE. By Capt. Howard Patterson. Price $1.

ON YACHT SAILING. By Thomas Fleming Day. Price $1.

HINTS TO YOUNG YACHT SKIPPERS. By Thomas Fleming Day. Price $1.

ON NAVIGATION SIMPLIFIED. By C. E. McArthur. Price $1.

HANDY JACK BOOK OF NAVIGATION TABLES. Price $1.

SOUTHWARD IN ROAMER. By H. C. Roome. Price $1.

ON RIVER AND CANAL TO LAKE CHAMPLAIN. Price $1.

INTRODUCTION

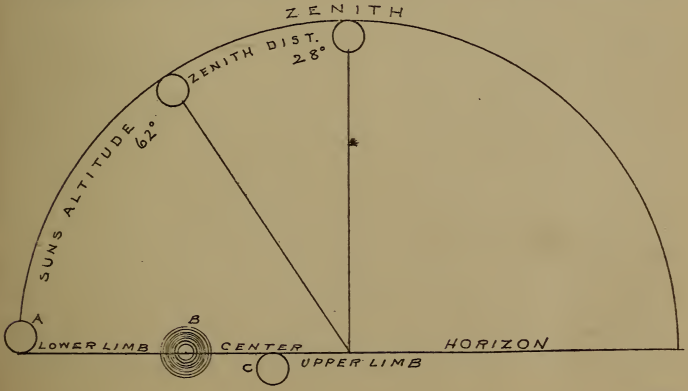
ALL books and instruments employed in navigation are made in large sizes. In the ordinary vessels upon which they are designed to be used this is no drawback, as there is usually space to be obtained in which to work of such ample dimensions as will permit the employment of large-sized charts, books and instruments. But in small vessels where room is restricted, both for storage and working, large and cumbersome apparatus is a hindrance and a nuisance. It is difficult enough to navigate upon a small vessel, without adding to the difficulties by using heavy instruments and bulky books. Only those who have worked, jammed in a corner of a yacht with the vessel in a heavy sea pitching and rolling, can understand how the mere weight and size of the books and charts used add to the burden of the work.

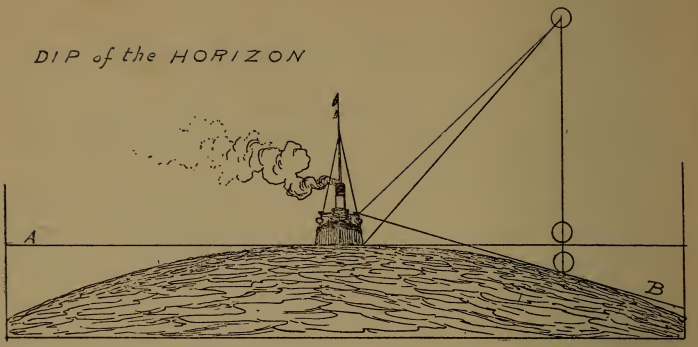
To in some measure decrease this cause of trouble, we have reduced the principal volume employed in navigation to a handier size than that supplied by the Government by curtailing its dimensions and by leaving out a number of unnecessary tables. This book is in such shape that it can be carried in the pocket and be had for quick reference, so that the small-boat navigator can sit down and work his problems in the most convenient spot.

ALTITUDE DIAGRAMS

What an altitude of the sun is short of 90° is called the zenith distance. Notice in diagram sun's altitude 62°, zenith distance 28°.

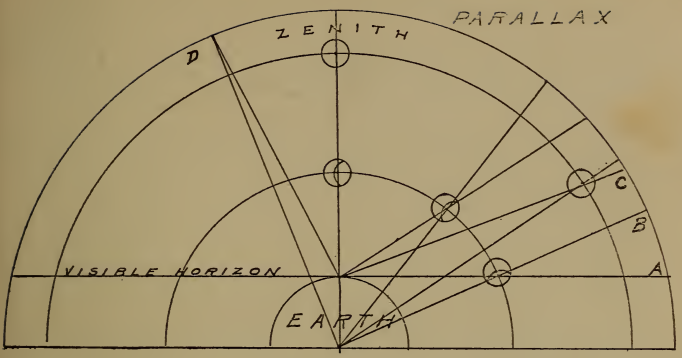
When the sun's lower edge is brought in contact with the horizon line it is called the lower limb, A. The sun's semi-diameter is always added in this case. When the sun's edges are blurred the center of the sun is brought to the horizon B. There is no correction for semi-diameter in this case. The figure at C shows the sun's upper limb, in which case the sun's semi-diameter is subtracted to get the true altitude of the sun's center.





DIP OF THE HORIZON

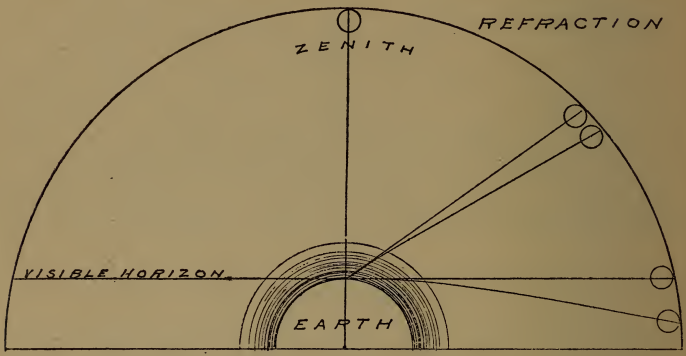
A depression caused by the elevation of the observer's eye above the level of the sea. If the eye could be at the surface of the water, on a level with the visible horizon A, there would be no dip, and that correction would not be used in working out your altitude. But on the bridge of the steamer your eye is raised quite a distance above the sea level, bringing the horizon line at a greater distance. You see over the hill, it is sometimes expressed. Your horizon in this case is depressed below the sea level, as shown by line B, making your altitude too great, as you will see by the angle. Being too great it is of course subtracted from the sextant altitude.



Parallax

The sun or moon should be observed from the center of the earth to get the proper angle. Parallax is therefore the difference between the angle as it would be if observed from the earth's center and from its surface. As will be seen in the diagram, this angle makes the altitude too small, it is therefore added. When the sun or moon is overhead there is no parallax. The parallax of the sun never exceeds 9″ of arc and is ignored by most navigators, but the moon is so near that its parallax is large. An observer on the earth's surface, when the moon was rising, would see her at A; an observer at the earth's center would see her at B, which is her true place. The difference of the two angles is called

her horizontal parallax. At C notice the sun being further away has less parallax, and the star at D, being so very far away, has none at all.



REFRACTION

When the rays of light from a star or other heavenly body enter our atmosphere it is bent downwards, as an oar seems to be bent, when seen in the clear water. The result is to make the star's altitude too great, this correction is therefore subtracted. When our object is on the horizon the refraction is greatest and vanishes altogether when it reaches the zenith. In the diagram it will be seen that the sun is still visible on the horizon but is really below it, refraction having thrown it up so that it is still visible.

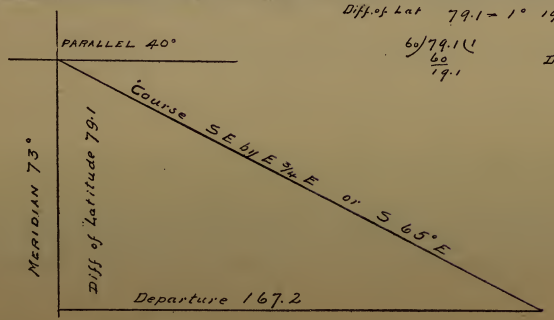
Compass Course	Variation	Deviation	Leeway	True Course	Distance	Latitude N	Latitude S	Departure E	Departure W
S E ½ E	¾ pt W	0	½ pt Starboard Tack.	SE by E ¾ E	185		79.1	167.2	
						Diff. of Longitude		215'	
		Enter table 1 or 2 and opposite the distance will be found		with the true Course and distance		185 miles Lat. 79.1 Dep. 167.2			

Lat. at last Noon	40°	00'	00"	N	Longitude last Noon	73°	00' 00" W
Diff. of Lat.	1	19	06	S	Diff. of Long.	3	35 .00 E
Latitude by D.R.	38	40	54		Longitude by D.R.	69	25 00 W
Lat. last Noon	40	00	00		Course made good	S 65° E	
Sum divided by 2	78	40	54		Distance " "	185 miles	
Middle Latitude	39	20	27				

With the above middle Lat. Enter table 2 at 39° and apply the departure 167.2 in the Latitude Column, which read from the top of the page if the degress are found there and from bottom if degress were found there. This time from top and to left, in dist. col. find 215' Diff Long.



The traverse table on the preceding page will show the whole operation of finding the latitude and longitude by dead reckoning, using tables 1 and 2 of Bowditch. (You already know how to correct the compass course for variation, leeway, etc.) The diagram explains the meaning of difference of latitude and departure by inspection. It may be said here that departure miles are honest miles all over the Mercator chart, when used opposite the parallel of latitude you are in. A degree of longitude is 60 miles wide only at the equator. At 40° North a degree would be only 46 miles. For that reason you find the middle latitude and apply your departure in the latitude column on that page, in table 2, to find your difference of longitude. On the traverse table the compass course is turned into a true course, then the operation of finding the latitude and departure is explained under it. The latitude and longitude at the last noon is put down. The difference of latitude found in the table is then divided by 60 to turn it into degrees and minutes, which is subtracted from last latitude, as the ship is going South and lessening the latitude. The result is the latitude by dead reckoning, which, added to the last latitude at last noon, and the sum divided by 2 gives the middle latitude. The next proceeding is explained on traverse table under this middle latitude, which is to get the difference of longitude, which is also turned into degrees, minutes and seconds of arc. As

you are going East and lessening the longitude, you will subtract this difference of longitude. The result is longitude by dead reckoning. Now with the difference of latitude and departure enter table 2 and make them compare as near as possible. The nearest comparison gives you 185 miles, and as the departure is the greater quantity, read from the bottom of the page and get 65° = course South, 65° East.

TABLE 2.

Difference of Latitude and Departure for 1° (179°, 181°, 359°).

N.B. The Admiralty knot = 6,080 ft.; 1 statute mile = 5,280 ft.

ON TAKING ALTITUDES AT SEA WITH THE SEXTANT

Correct Clock for Change of Longitude

About an hour before taking the meridian altitude, correct the ship's clock, by adding four minutes to its time for every degree sailed East, subtracting four minutes for every degree sailed West, since it was last set. If the first day at sea, and the clock has not been changed from mean to apparent or sun time, do so now, as the sun time differs from mean time (always used ashore) as much as sixteen minutes at times. To change from mean time to apparent, take from the Nautical Almanac the equation of time for the date and apply it according to the directions always found at the top of the equation column. The navigator sometimes misses the meridian altitude through overlooking change of time since the last noon. Having found the apparent time at ship, it is usual to bring the sextant on deck about fifteen minutes before noon. Before taking the observation, examine the instrument for index error and make a note of it if any is found. Then turn down one of the shade glasses (a neutral tint is much better than red or green) to shield the eye from the strong glare of the sun's image.

Set the index at 0. Then direct the sight through the sight vane directly at the sun, and its colored image

will appear in the horizon glass. The index, or sliding limb, as it is often called, is now moved forward. In proportion as it is moved the image will descend. Follow it down by bringing the sextant gradually to the vertical; or holding the sextant in a vertical position, direct the sight through the sight vane and horizon glass to that part of the horizon directly under the sun. Move the index forward and the sun will soon descend to the horizon; when it touches make the contact perfect with the tangent screw. If you wish to use the telescope it can now be adjusted.

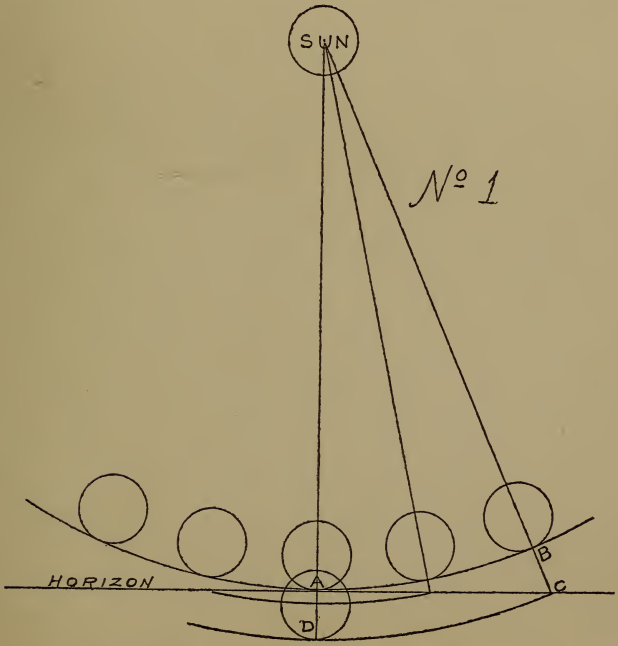
Approximating the Altitude

Many navigators approximate the meridian altitude beforehand and in taking star sights nearly always. To do this in the case of stars, planets or the sun, take the declination of the star or sun from the Nautical Almanac and then roughly estimate the latitude by dead reckoning. If latitude and declination are both North, take their difference and the result from 90° and you will have the altitude nearly. If one is N. and the other S. add them together and take the result from 90°.

Thus: Latitude	40° N.	40° N.
Declination	23 N.—	23 S.+
	17	63
	90 —	90 —
Approx. Alt.	73°	27°

Keep Tangent Screw Free

Place this altitude on the sextant, carefully noticing that the tangent screw has more than enough play to finish the altitude. There is nothing more annoying in taking a sight than to find that screw jammed. If so, never try to force it; unclamp it and give several turns the other way, and reset the altitude. Then direct your



sight to the horizon under the sun and you will see her image the color of the shade glass on or near the horizon. While keeping the eye to the sight vane give the instrument a slow swinging movement from side to side. The sun's image will seem to skim the horizon, describing the lower edge of a circle. The lowest edge of this arc will mark the point of highest altitude. (See diagram 1.)

Use Care in Altitudes Near 90°

The sun's image must be kept in contact with the horizon by turning the tangent screw until her highest altitude has been reached. She will then remain steady for a minute or more unless your altitude is 90° or near it, which is the case when your latitude and the sun's declination are the same or nearly so. In this case watch very steadily, keep her image on the lowest point of the arch, close up the slightest streak of daylight between her lower limb and the horizon line as she goes up, for when she gets to the highest point of the meridian circle, her bearing will change in a flash. You must be very careful of that. If the sun falls the slightest degree never raise her to the horizon, for she has passed the meridian. In low latitudes she rises much faster when near meridian than in high ones, where her motion is slow, particularly in Winter, when the altitude is very low.

Always Swing the Sextant Around the Line of Sight

When sure the sun has ceased to rise, call eight bells and read off your altitude. It is just as well, however, to keep watching her until she is seen to sensibly dip below the edge of the horizon. To impress the importance of swinging the sextant I will call attention to a little thing that sometimes occurs. Say that you are running to the Eastward before the wind in a lively boat, and your latitude somewhere North of the sun. The sun, when near meridian, will be at right angles to the yacht's course and at *A* (diagram 1). As you follow up the sun you will now and then take a short rest to ease your arm. Very soon you direct your sight to the same apparent point of the horizon you last looked at, that is, directly to windward. You are surprised at the jump the sun has taken. The index must have slipped, you think. The altitude is corrected and clamped good. A very short interval and you look again; you are now surprised at the slump she has taken. If close on noon and you are inexperienced (as you would be), you may get rattled. You will probably find out what's up in time to come out all right, unless you are near the sun's latitude. In that case the altitude may be lost. When the second look was taken the yacht had come to, a little to the Southward of her course. Then directing your sight to the same *apparent* point of the

horizon brought the sun's image to the right of the vertical at *B* above the horizon; it was then drawn down to the horizon at *C*. When the boat goes off on her course, the image is under the vertical again at *D* and away below the horizon. Always swing the sextant around the line of sight and you will never lose the sun's bearing.

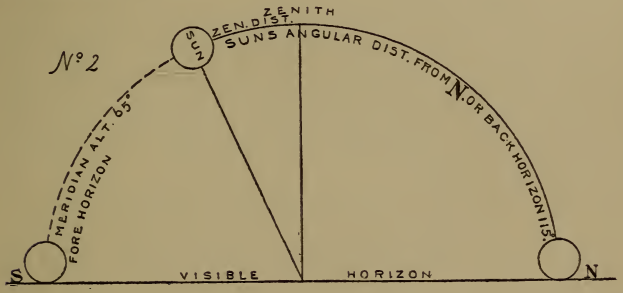
I noticed in the Bahamas when taking a meridian altitude that the dip of the horizon changed while looking at it through the glass. The sun would be a little above, then a little below the sea horizon, which showed above a chain of low-lying sun-baked rocks (double-headed shots) less than half a mile away. The radiation of heat from the rocks was the cause of the variation.

Back Observations with the Sextant

When the horizon under the sun is obscured by land and the sun has a meridian altitude of say 65°, you can turn your back to the sun, and bring its lower limb to the opposite point of the horizon. A quadrant, of course, will not measure it. (The upper limb under the sun becomes the lower limb when opposite.) This angle subtracted from 180° will give the altitude of the *upper limb*. This must be corrected for semi-diameter and dip, of course, to get the true altitude of the sun's center.

If you suspect much refraction on the horizon, you can take the *lower limb* of both the fore and back hori-

zons and half the *difference* of the two altitudes will be the zenith distance of the center. In this case there will be no correction for semi-diameter, dip, refraction, or index error. Any displacement of the sea horizon will be equal all around. As the sextant cannot measure over 120° your altitude under the sun must be 60° or more. (See diagram 2 for back horizon.) As soon as you are sure the sun has stopped rising, take the back horizon at once or she may dip. If she does, the other will answer as usual.



Without the Telescope, Observation in Heavy Sea Much Easier

Many find it hard to get a satisfactory sight from a small vessel in a heavy seaway. Most of them use the telescope, which is nearly the whole trouble. Without it you won't have the slightest difficulty, no matter how hard the boat is pitching into it. When using it

you will have trouble enough. In a short sea the sun's image is constantly lost out of the field of vision, and if the boat runs off her course at the same time, you won't be able to find it at all. It is to begin all over again, and when she is located you won't find her where you expected. It will not harm to say, turn the peak of your cap around behind your head. Many a chap has wondered where in thunder the sun was when his hat was hiding her. As just mentioned, the sun's image, large as it is, will be snatched out of the field of vision so often by the heaving and pitching of the boat, that an observer may become so arm-weary that he will in desperation accept a doubtful altitude. But without that tube the boat can do any amount of diving. You have all outdoors for your field of vision and can make the sun do what you will.

When Horizon is Obstructed by High Seas

Don't worry about the center of the sight vane; just look through the collar that the telescope screws into and the result will be found quite accurate. The best place on a yacht to shoot the sun, if she bears so

that you can do so, is from the companionway. There you are strongly braced and avoid the risk of getting your sextant injured in moving around. If the sea is running very high and constantly obstructing your view of the horizon level, keep pulling the sun down to what you estimate to be the horizon line as you wait for the yacht to rise on a high sea. You will be ready when she rises and she will always be up long enough for a careful swing and turn of the tangent screw to finish the work you had already begun. If you have only fleeting glimpses of the sun over your stormy horizon and cannot wait, then notice any level you can see to the right or left of the sun's bearing and imagine a straight line continued from that behind the rising wave and, swinging the sextant, make the sun's lower limb skim that imaginary line (diagram 3). With a little experience you will get an almost exact altitude. With some practice you will also be able to set your sextant to nearly the exact altitude, a valuable thing when in a hurry, or without using the telescope direct your sight as usual under the sun and drop her right down to the horizon in an instant.

On Taking Your Own Time

If the boat is jumping pretty lively, don't attempt to go to the chronometer carrying the sextant with you. Hand it to some one if it should be necessary to take

your own time. Many a good instrument has been spoiled by the owner being thrown down to leeward with it. I had some narrow escapes before I was cured. I saved the sextant always, but on one occasion was put badly out of adjustment myself. You will find it hard to count seconds and go easily to the chronometer at such times. In taking your own time a perfect way is to use the chronograph watch,—an inexpensive one will do. Notice when using that the hand that ticks off the seconds has not been accidently started, then at the instant of contact touch the spring. You need not hurry to the chronometer. Wait until the chronometer shows an even number of seconds, then snap the spring which will stop the second hand. After you write down your chronometer time notice the number of seconds shown on the watch, which you will subtract from the chronometer time, then touch the spring again and it will fly back to its place. If the sextant will fit in the box that way, it is well to leave it clamped at the last altitude. You may be glad to refer to it again. It is not uncommon to make an error in reading off, particularly if you have a poor light at night. When reading let the light fall on it from directly in front, also keep the eye vertically over the cutting on the vernier.

Low Altitudes

It is best not to use altitudes of less than 10° if it

can be avoided, on account of the large amount of refraction. If such altitudes must be taken, use the upper limb of the sun. In the Gulf Stream, where the water is much warmer than the air, the sea horizon is depressed more than the amount allowed in the tables. If the difference in temperature is considerable it will be safe to take a couple of miles from the altitude in a. m. and p. m. sights. It is said that the greatest amount of refraction is found before an Easterly.

Time for Taking Stars

On taking altitudes of the stars or planets the best time is at twilight and before sunrise, or when the moon is up. The horizon at those times is well defined. The altitude of the Pole Star, corrected for dip and refraction, is generally not far from the latitude of the observer and at times almost exactly so. When ε Ursa Majoris (called Alioth) and Polaris are the same distance above the horizon, that is, a line joining the two would be parallel to it, the Star is then six hours from the meridian and its altitude is then nearly the same as the elevation of the pole or the latitude of the observer. When well down toward the equator, say 10° North, it is so low that it is lost in the haze over the horizon and cannot be used. From 20° Northward it can be plainly seen.

The Pole Star

In taking the Pole Star roughly estimate your latitude, then put that on the sextant and a little more. Then direct your sight to that point on the horizon directly under the star. You may not see it at first, as the star is at times quite dim. But it is there, and after your eyes accustom themselves to the search, the little pin-point of light will be seen against the dark water below the horizon line. It will then be easy to get the right altitude.

Use Both Eyes for Stars

It is always best to approximate the altitudes of stars if there is any sea on. To follow one of those dancers down in a seaway, particularly if you use a telescope, is no easy task. She will wiggle away so often that before you get her to the horizon you will care very little what your latitude may be. When the horizon is ill defined, you can get your latitude closely by taking the altitude of one star to the North and another to the South and, although on account of the poor horizon both may be inaccurate, the two latitudes added together and divided by two will be close to the truth. If you have a good star telescope it may help when the horizon is dim. In taking the altitude of a star for longitude, remove the telescope, set the index at 0, then

direct the sight to the star, *using both eyes.* Move the index forward and the star will move downward; carefully follow it down until it reaches the horizon. If you prefer to use your telescope you may now screw it in. Most navigators have the tube marked at focus with a strong scratch. Always carefully wipe off the arc and also the silvered glasses of the sextant after moon or star observations, as they are always quite wet with dew. Use a *very soft* rag or piece of chamois skin on the arc, or you will soon ruin it (it is *very easily* scratched); also be very gentle with the mirrors or they may be put out of adjustment.

Observations of the Moon

In taking altitudes of the moon or stars it is hardly necessary to say that no shade glass is used. Observations of the moon are taken the same as those of the sun. The lower limb is always to be preferred, unless the horns are down, when the upper limb is used. When the moon casts a reflection on the horizon you can get a good observation, but when it is obscured by cloud shadows you can do nothing.

Altitudes in Thick Weather

When the sky is overcast and it is very necessary to get a sight, keep a sharp lookout in the direction in

which the sun should be seen. If you notice that, though clouded over, it is a little trying to the eyes, there is a probability that it will break through. Get your sextant ready and if the sun appears as only a blur of light, take the center of that, and the time, then wait a while and see if you get anything better. You may get a bright spot or a snap-shot at one of the limbs. If you do not, the first blur will be quite valuable and will give approximately your position. Do not correct for semi-diameter when taking the center of the blurred spot. Going to Bermuda in the yawl Hyperion, in 1907, we had thick, squally weather on the morning of our arrival. At 7 a. m. the reefs bore by our reckoning S.S.E. about 50 miles, and we wanted within the usual limit of error to be sure. At 8 a. m. it lightened up a bit and getting ready, took altitudes of the center of several bright spots, marking off the last as we got better. The last one seemed the faint ghost of the lower limit. We worked that and the center of the blur taken five minutes before. The mean of the two, which were five miles apart, was close to our reckoning and St. Davids Head was made four hours later.

In slightly foggy weather it is sometimes possible to get our observation by getting very close to the water. In clear weather the higher the elevation the better.

RUDDER ON SERIES

ON NAVIGATION SIMPLIFIED

By C. E. McARTHUR

Late United States Licensed Master Steam and Sail Ships
Also British Certificate of Competency as Master

THE author has worked out and explained in this book all the problems required by the United States Local Inspectors' examination of masters and mates in a simple, understandable way, that anyone can grasp.

Illustrations of the shortest sea methods of practical branches of navigation and nautical astronomy.

Price $1.00 Postpaid

Send for Complete Catalogue of Books for the Yachtsman's Library

THE RUDDER PUBLISHING COMPANY
9 Murray Street New York City

RUDDER RULE SERIES

Questions and Answers
on the
Rules of the Road

Especially prepared for the instruction of yacht and power boat skippers. Completely covering the subjects of Lights, Whistles, Fog Signals, etc. Every yachtsman should buy and study this book.

Price 25c Postpaid

IN QUANTITIES TO YACHT CLUBS

100 copies, $20.00; 50 copies, $10.00
25 copies, $5.00

Just what we have all been looking for—a pocket course and distance book for Long Island Sound. No more bothering with charts at night. It is all here in a hand full—the courses at a glance. The helmsman's always ready watch-mate—

The Pocket Course Book of Long Island Sound.

Compiled by Horace Barclay, Master Mariner.

Price Twenty-five Cents.

THE RUDDER PUBLISHING CO.
9 Murray St., New York

On River and Canal

to

Lake Champlain

Albany to Whitehall by Canal. Jamaica Bay to Lake Champlain. New York City to Lake George. Philadelphia to Ticonderoga and Return

How to Get a Permit. Gives Distances from Point to Point on Hudson River. Lights Between Troy and New York City. Hotels and Taverns. Anchorages in Hudson River. Lengths and Levels of Canal Locks. Distance Table of Locks

---

Invaluable to any one cruising on the Hudson or going to the Lakes
